

Many software teams begin with Github and fancy it has all the tools necessary to get started. And it does!

However, as your team grows and the complexity of your software increases, managing your roadmap, planning, and the business in general becomes increasingly difficult with Github Issues, Milestones, Pages, etc.

That's precisely what the team at Atlassian has solved with Jira, Confluence, and their world class software suite.

So you're ready to upgrade to Jira and implement some real processes and integrations across enterprise tools, and join the big leagues. How do you migrate all your useful data from Github to Jira?

## [Github2Jira](#)

That's precisely the problem I had to solve this week, and I'd love to share the tool I built to do it. Documentation, examples and everything you need can be found at the github repository shared below (ironic, I know).
